#### Data Information

Ge the data from: http://www.nyc.gov/html/tlc/html/about/trip\_record\_data.shtml (2016 data) The data used in the attached datasets were collected and provided to the NYC Taxi and Limousine Commission (TLC)

# Information on taxis:

#### Yellow Taxi: Yellow Medallion Taxicabs

These are the famous NYC yellow taxis that provide transportation exclusively through street-hails. The number of taxicabs is limited by a finite number of medallions issued by the TLC. You access this mode of transportation by standing in the street and hailing an available taxi with your hand. The pickups are not pre-arranged.

#### For Hire Vehicles (FHVs)

FHV transportation is accessed by a pre-arrangement with a dispatcher or limo company. These FHVs are not permitted to pick up passengers via street hails, as those rides are not considered pre-arranged.

### Green Taxi: Street Hail Livery (SHL)

The SHL program will allow livery vehicle owners to license and outfit their vehicles with green borough taxi branding, meters, credit card machines, and ultimately the right to accept street hails in addition to pre-arranged rides.

Credits: Quora

#### Footnote:

In the given notebook we are considering only the yellow taxis for the time period between Jan - Mar 2015 & Jan - Mar 2016

# **Data Collection**

We Have collected all yellow taxi trips data from jan-2015 to dec-2016(Will be using only 2015 data)

file name	file name size	number of records	number of features
yellow_tripdata_2016-01	1. 59G	10906858	19

```
month.fare_amount.sum().visualize()
```

#### Out[4]:

# Features in the dataset:

Description	Field Name
A code indicating the TPEP provider that provided the record.  Creative Mobile Technologies  VeriFone Inc.	VendorID
The date and time when the meter was engaged.	tpep_pickup_datetime
The date and time when the meter was disengaged.	tpep_dropoff_datetime
The number of passengers in the vehicle. This is a driver-entered value.	Passenger_count
The elapsed trip distance in miles reported by the taximeter.	Trip_distance

Pickup_longitude	Longitude where the meter was engaged.
Pickup_latitude	Latitude where the meter was engaged.
RateCodeID	The final rate code in effect at the end of the trip.  Standard rate  JFK 3.  Newark 4.  Nassau or Westchester 5.  Group ride
Store_and_fwd_flag	This flag indicates whether the trip record was held in vehicle memory before sending to the vendor, aka "store and forward," because the vehicle did not have a connection to the server. Y= store and forward trip N= not a store and forward trip
Dropoff_longitude	Longitude where the meter was disengaged.
Dropoff_latitude	Latitude where the meter was disengaged.
Payment_type	A numeric code signifying how the passenger paid for the trip. Credit card Cash Cash No charge Dispute Unknown Code signifying how the passenger paid for the trip. Credit card Cash No charge Dispute Voided trip
Fare_amount	The time-and-distance fare calculated by the meter.
Extra	$\label{thm:miscellaneous} \mbox{Miscellaneous extras and surcharges. Currently, this only includes. the $0.50 \mbox{and} 1$ rush hour and overnight charges.}$
MTA_tax	0.50 MTA tax that is automatically triggered based on the metered rate in use.
Improvement_surcharge	0.30 improvement surcharge assessed trips at the flag drop, the improvement surcharge began being levied in 2015.
Tip_amount	Tip amount – This field is automatically populated for credit card tips.Cash tips are not included.
Tolls_amount	Total amount of all tolls paid in trip.
Total_amount	The total amount charged to passengers. Does not include cash tips.

# **ML Problem Formulation**

Time-series forecasting and Regression

- To find number of pickups, given location cordinates(latitude and longitude) and time, in the query reigion and surrounding regions.

To solve the above we would be using data collected in Jan - Mar 2015 to predict the pickups in Jan - Mar 2016.

# **Performance metrics**

- 1. Mean Absolute percentage error.
- 2. Mean Squared error.

# **Data Cleaning**

In this section we will be doing univariate analysis and removing outlier/illegitimate values which may be caused due to some error

# In [5]:

```
#table below shows few datapoints along with all our features
month.head(5)
```

## Out[5]:

	VendorID	tpep_pickup_datetime	tpep_dropoff_datetime	passenger_count	trip_distance	pickup_longitude	pickup_latitude	RateCode

# 1. Pickup Latitude and Pickup Longitude

It is inferred from the source <a href="https://www.flickr.com/places/info/2459115">https://www.flickr.com/places/info/2459115</a> that New York is bounded by the location cordinates (lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with pickups which originate within New York.

#### In [6]:

**Observation:-** As you can see above that there are some points just outside the boundary but there are a few that are in either South america, Mexico or Canada

# 2. Dropoff Latitude & Dropoff Longitude

It is inferred from the source <a href="https://www.flickr.com/places/info/2459115">https://www.flickr.com/places/info/2459115</a> that New York is bounded by the location cordinates (lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with dropoffs which are within New York.

المرازين ببلا

```
# Plotting dropoff cordinates which are outside the bounding box of New-York
# we will collect all the points outside the bounding box of newyork city to outlier locations
outlier locations = month[((month.dropoff longitude <= -74.15) | (month.dropoff latitude <= 40.5774
                   (month.dropoff longitude >= -73.7004) | (month.dropoff latitude >= 40.9176))]
# creating a map with the a base location
# read more about the folium here: http://folium.readthedocs.io/en/latest/quickstart.html
\# note: you dont need to remember any of these, you dont need indeepth knowledge on these maps and
plots
map osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
# we will spot only first 100 outliers on the map, plotting all the outliers will take more time
sample_locations = outlier_locations.head(10000)
for i,j in sample locations.iterrows():
    if int(j['pickup latitude']) != 0:
        folium.Marker(list((j['dropoff latitude'],j['dropoff longitude']))).add to(map osm)
map osm
```

Observation:- The observations here are similar to those obtained while analysing pickup latitude and longitude

## 3. Trip Durations:

According to NYC Taxi & Limousine Commision Regulations the maximum allowed trip duration in a 24 hour interval is 12 hours.

```
In [8]:
```

```
#The timestamps are converted to unix so as to get duration(trip-time) & speed also pickup-times in unix are used while binning

# in out data we have time in the formate "YYYYY-MM-DD HH:MM:SS" we convert this sting to python to ime formate and then into unix time stamp

# https://stackoverflow.com/a/27914405

def convert_to_unix(s):
    return time.mktime(datetime.datetime.strptime(s, "%Y-%m-%d %H:%M:%S").timetuple())
```

```
# we return a data frame which contains the columns
# 1.'passenger count' : self explanatory
# 2.'trip distance' : self explanatory
# 3.'pickup_longitude' : self explanatory
# 4.'pickup latitude' : self explanatory
# 5.'dropoff_longitude' : self explanatory
# 6.'dropoff latitude' : self explanatory
# 7.'total amount' : total fair that was paid
# 8.'trip_times' : duration of each trip
# 9.'pickup times : pickup time converted into unix time
# 10.'Speed' : velocity of each trip
def return with trip times(month):
   duration = month[['tpep pickup datetime','tpep dropoff datetime']].compute()
   #pickups and dropoffs to unix time
   duration_pickup = [convert_to_unix(x) for x in duration['tpep_pickup_datetime'].values]
   duration drop = [convert to unix(x) for x in duration['tpep dropoff datetime'].values]
    #calculate duration of trips
   durations = (np.array(duration drop) - np.array(duration pickup))/float(60)
   #append durations of trips and speed in miles/hr to a new dataframe

#### In [56]:

```
# why we choose, these methods and which method is used for which data?

# Ans: consider we have data of some month in 2015 jan 1st, 10 _ _ _ 20, i.e there are 10 pickups that are happened in 1st

# 10st 10min intravel, 0 pickups happened in 2nd 10mins intravel, 0 pickups happened in 3rd 10min intravel

# and 20 pickups happened in 4th 10min intravel.

# in fill_missing method we replace these values like 10, 0, 0, 20

# where as in smoothing method we replace these values as 6,6,6,6,6, if you can check the number of pickups

# that are happened in the first 40min are same in both cases, but if you can observe that we look ing at the future values

# wheen you are using smoothing we are looking at the future number of pickups which might cause a data leakage.

# so we use smoothing for jan 2015th data since it acts as our training data

# and we use simple fill_misssing method for 2016th data.
```

```

# **Modelling: Baseline Models**

Now we get into modelling in order to forecast the pickup densities for the months of Jan, Feb and March of 2016 for which we are using multiple models with two variations

- 1. Using Ratios of the 2016 data to the 2015 data i.e  $R_{\rm t} = P_{\rm r}^{2016}/P_{\rm r}^{2015}$
- 2. Using Previous known values of the 2016 data itself to predict the future values

## Simple Moving Averages

The First Model used is the Moving Averages Model which uses the previous n values in order to predict the next value

Using Ratio Values -  $R_t = (R_{t-1} + R_{t-2} + R_{t-3} \dots R_{t-n})/n$ 

```
In [85]:
```

```
def MA R Predictions(ratios, month):
    predicted ratio=(ratios['Ratios'].values)[0]
    error=[]
    predicted values=[]
    window size=3
    predicted ratio values=[]
    for i in range(0,4464*40):
        if i%4464==0:
            predicted ratio values.append(0)
            predicted values.append(0)
            error.append(0)
            continue
        predicted ratio values.append(predicted ratio)
        predicted_values.append(int(((ratios['Given'].values)[i])*predicted_ratio))
        error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted ratio)-(ratios['Pred
iction'].values)[i],1))))
       if i+1>=window size:
            predicted ratio=sum((ratios['Ratios'].values)[(i+1)-window size:(i+1)])/window size
        else:
            predicted ratio=sum((ratios['Ratios'].values)[0:(i+1)])/(i+1)
    ratios['MA R Predicted'] = predicted values
    ratios['MA R Error'] = error
    mape_err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].v
```

```
alues))
mse_err = sum([e**2 for e in error])/len(error)
return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 3 is optimal for getting the best results using Moving Averages using previous Ratio values therefore we get  $R_t = (R_{t-1} + R_{t-2} + R_{t-3})/3$ 

Next we use the Moving averages of the 2016 values itself to predict the future value using  $P_t = (P_{t-1} + P_{t-2} + P_{t-3}, \dots, P_{t-n})/n$ 

In [86]:

```
def MA P Predictions(ratios, month):
   predicted value=(ratios['Prediction'].values)[0]
   error=[]
   predicted values=[]
   window size=1
   predicted ratio values=[]
   for i in range(0,4464*40):
       predicted_values.append(predicted_value)
       error.append(abs((math.pow(predicted_value-(ratios['Prediction'].values)[i],1))))
       if i+1>=window size:
           predicted_value=int(sum((ratios['Prediction'].values)[(i+1)-window_size:
(i+1)])/window size)
        else:
            predicted_value=int(sum((ratios['Prediction'].values)[0:(i+1)])/(i+1))
   ratios['MA P Predicted'] = predicted values
   ratios['MA_P_Error'] = error
   mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].v
alues))
   mse err = sum([e**2 for e in error])/len(error)
   return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 1 is optimal for getting the best results using Moving Averages using previous 2016 values therefore we get  $P_t = P_{t-1}$ 

# **Weighted Moving Averages**

The Moving Avergaes Model used gave equal importance to all the values in the window used, but we know intuitively that the future is more likely to be similar to the latest values and less similar to the older values. Weighted Averages converts this analogy into a mathematical relationship giving the highest weight while computing the averages to the latest previous value and decreasing weights to the subsequent older ones

Weighted Moving Averages using Ratio Values -  $R_t = (N*R_{t-1} + (N-1)*R_{t-2} + (N-2)*R_{t-3}....1*R_{t-n})/(N*(N+1)/2)$ 

In [87]:

```
def WA R Predictions(ratios, month):
    predicted ratio=(ratios['Ratios'].values)[0]
   alpha=0.5
    error=[]
    predicted values=[]
    window_size=5
    predicted ratio values=[]
    for i in range(0,4464*40):
        if i%4464==0:
            predicted_ratio_values.append(0)
            predicted values.append(0)
            error.append(0)
        predicted ratio values.append(predicted ratio)
        predicted values.append(int(((ratios['Given'].values)[i])*predicted ratio))
        error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted ratio)-(ratios['Pred
iction'].values)[i],1))))
        if i+1>=window size:
            sum values=0
            sum of coeff=0
            for j in range(window_size,0,-1):
                sum values += j*(ratios['Ratios'].values)[i-window size+j]
                sum of coeff+=i
```

```
predicted_ratio=sum_values/sum_of_coeff
else:
    sum_values=0
    sum_of_coeff=0
    for j in range(i+1,0,-1):
        sum_values += j*(ratios['Ratios'].values)[j-1]
        sum_of_coeff+=j
    predicted_ratio=sum_values/sum_of_coeff

ratios['WA_R_Predicted'] = predicted_values
    ratios['WA_R_Error'] = error
    mape_err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].v
alues))
    mse_err = sum([e**2 for e in error])/len(error)
    return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 5 is optimal for getting the best results using Weighted Moving Averages using previous Ratio values therefore we get  $R_t = (5*R_{t-1} + 4*R_{t-2} + 3*R_{t-3} + 2*R_{t-4} + R_{t-5})/15$ 

Weighted Moving Averages using Previous 2016 Values -  $P_t = (N*P_{t-1} + (N-1)*P_{t-2} + (N-2)*P_{t-3}....1*P_{t-n})/(N*(N+1)/2)$ 

In [88]:

```
def WA P Predictions(ratios, month):
   predicted value=(ratios['Prediction'].values)[0]
    error=[]
   predicted values=[]
    window size=2
    for i in range(0,4464*40):
       predicted values.append(predicted value)
        error.append(abs((math.pow(predicted value-(ratios['Prediction'].values)[i],1))))
        if i+1>=window size:
            sum values=0
            sum of coeff=0
            for j in range(window size, 0, -1):
                sum values += j*(ratios['Prediction'].values)[i-window size+j]
                sum of coeff+=j
            predicted_value=int(sum_values/sum of coeff)
        else:
            sum values=0
            sum of coeff=0
            for j in range(i+1,0,-1):
                sum values += j*(ratios['Prediction'].values)[j-1]
                sum of coeff+=j
            predicted value=int(sum values/sum of coeff)
    ratios['WA P Predicted'] = predicted values
    ratios['WA P Error'] = error
    mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].v
alues))
   mse err = sum([e^{**2} for e in error])/len(error)
    return ratios,mape err,mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 2 is optimal for getting the best results using Weighted Moving Averages using previous 2016 values therefore we get  $P_t = (2 * P_{t-1} + P_{t-2})/3$ 

# **Exponential Weighted Moving Averages**

https://en.wikipedia.org/wiki/Moving\_average#Exponential\_moving\_average. Through weighted averaged we have satisfied the analogy of giving higher weights to the latest value and decreasing weights to the subsequent ones but we still do not know which is the correct weighting scheme as there are infinetly many possibilities in which we can assign weights in a non-increasing order and tune the hyperparameter window-size. To simplify this process we use Exponential Moving Averages which is a more logical way towards assigning weights and at the same time also using an optimal window-size.

In exponential moving averages we use a single hyperparameter alpha (a) which is a value between 0 & 1 and based on the value of the hyperparameter alpha the weights and the window sizes are configured.

For eg. If  $\alpha = 0.9$  then the number of days on which the value of the current iteration is based is  $\sim 1/(1-\alpha) = 10$  i.e. we consider values

10 days prior before we predict the value for the current iteration. Also the weights are assigned using 2/(N+1) = 0.18, where N = number of prior values being considered, hence from this it is implied that the first or latest value is assigned a weight of 0.18 which keeps exponentially decreasing for the subsequent values.

```
R_{t}^{'} = \alpha * R_{t-1} + (1 - \alpha) * R_{t-1}^{'}
```

```

# Comparison between baseline models

We have chosen our error metric for comparison between models as **MAPE** (**Mean Absolute Percentage Error**) so that we can know that on an average how good is our model with predictions and **MSE** (**Mean Squared Error**) is also used so that we have a clearer understanding as to how well our forecasting model performs with outliers so that we make sure that there is not much of a error margin between our prediction and the actual value

```

# **Assignments**

```
In [265]:
```

```
Task 1: Incorporate Fourier features as features into Regression models and measure MAPE. <br/>
Task 2: Perform hyper-parameter tuning for Regression models.
2a. Linear Regression: Grid Search
2b. Random Forest: Random Search
2c. Xgboost: Random Search
Task 3: Explore more time-series features using Google search/Quora/Stackoverflow to reduce the MAPE to < 12%
'''
